Comparative genomics has been part of the human genome project right from the start. The original plan was to sequence the human genome and the genomes of a small number of model organisms, including bacteria, yeast, fruit fly, the nematode worm *Caenorhabditis elegans*, and the mouse (National Institutes of Health and Department of Energy 1990).

Comparative genomics is a field of biological research in which the genomic features of different organisms are compared. The genomic features may include the DNA sequence, genes, gene order, regulatory sequences, and other genomic structural landmarks. In this branch of genomics, whole or large parts of genomes resulting from genome projects are compared to study basic biological similarities and differences as well as evolutionary relationships between organisms. The major principle of compara

The first step in comparative genomics is determining the correct correspondence of chromosomal segments and functional elements across the species compared. This involves determining orthologous segments of DNA that descend from the same region in the common ancestor of the species compared, and paralogous regions that arose by duplication events
